Slipping Clutches are usually a safety feature and are designed to slip at some preset torque so protecting against damage. Dog Clutches are quite different to any of the above in that they do not rely on friction and it is generally necessary for the two shafts to be stationary when the clutch is either engaged or disengaged.

In order to understand how it works, we are going to use the single disc dry clutch as an example. The multi-disc, wet clutch is going to be explained in details later on. In the image below you can see a schematic of a single disc clutch.The engine crankshaft, flywheel, spring (coil or diaphragm) and pressure plate are all connected together, they are fixed to each other.

There is a loss of power in it due to slipping and friction. It is not capable of transferring a high amount of power and it shoes slip in heavy load condition. It experiences overheating problem. Its engagement depends upon the speed of the driving shaft. APPLICATION OF CENTRIFUGAL CLUTCH Centrifugal clutches are mainly used as a start-up clutch.

The clutch actuation system is static, relative to the body of the vehicle. The clutch pressure plate and diaphragm spring are rotating together with the crankshaft of the internal combustion engine. The clutch release device has to provide the link between a static element (slave cylinder piston/pushrod) and a moving element (diaphragm spring).
